

Diverse Mechanisms of International Migration: The Mexico-U.S. Case

Filiz Garip
Harvard University

There are 12 million Mexican-born in the United States, about half of them are undocumented.

Who are these migrants? What brings them here?

Many theories, from multiple disciplines, speak to these questions.

Neoclassical economics:

Individuals migrate to maximize earnings.

New economics of labor migration:

Families send migrants to diversify risks to earnings.

Cumulative causation:

Individuals follow former migrants in family or community.

These theories are not mutually exclusive.

Empirical work fails to capture causal heterogeneity.

Most studies characterize the average case and select a theory that best accounts for that case.

This study considers the following:

Individuals might migrate for different reasons.

Different theories might apply to different groups or under different circumstances.

How do we capture the heterogeneity in migration behavior?

Strategy

1. Fix the outcome and study only the migrants.

Strategy

1. Fix the outcome and study only the migrants.
2. Search for different groups among migrants.
Groups are defined by shared configurations of attributes. Assumption: Individuals with similar attributes face similar opportunity structures.

Strategy

1. Fix the outcome and study only the migrants.
2. Search for different groups among migrants.
Groups are defined by shared configurations of attributes. Assumption: Individuals with similar attributes face similar opportunity structures.
3. Study the conditions that set apart each group from the other groups as well as non-migrants.

Who migrates?

When?

Why?

Data

Mexican Migration Project (MMP) surveyed about 200 randomly-selected households in 143 Mexican communities from 24 states between 1982 and 2013.

Our sample contains 19,243 migrants observed during their first U.S. trip between 1965 and 2010.

Method: Cluster analysis

Discovers groups with similar attributes in data

Method: Cluster analysis

How it works:

1. Choose and scale the relevant attributes
2. Choose an algorithm: K-means
3. Choose a similarity measure: City-block distance
4. Determine K, the number of clusters, using cluster validation measures

Who migrates?

URBAN MIGRANTS

Each migrant group becomes prevalent in a particular period.

Are differences between groups real or are they an artifact of secular trends in Mexico?

TRENDS IN EDUCATION

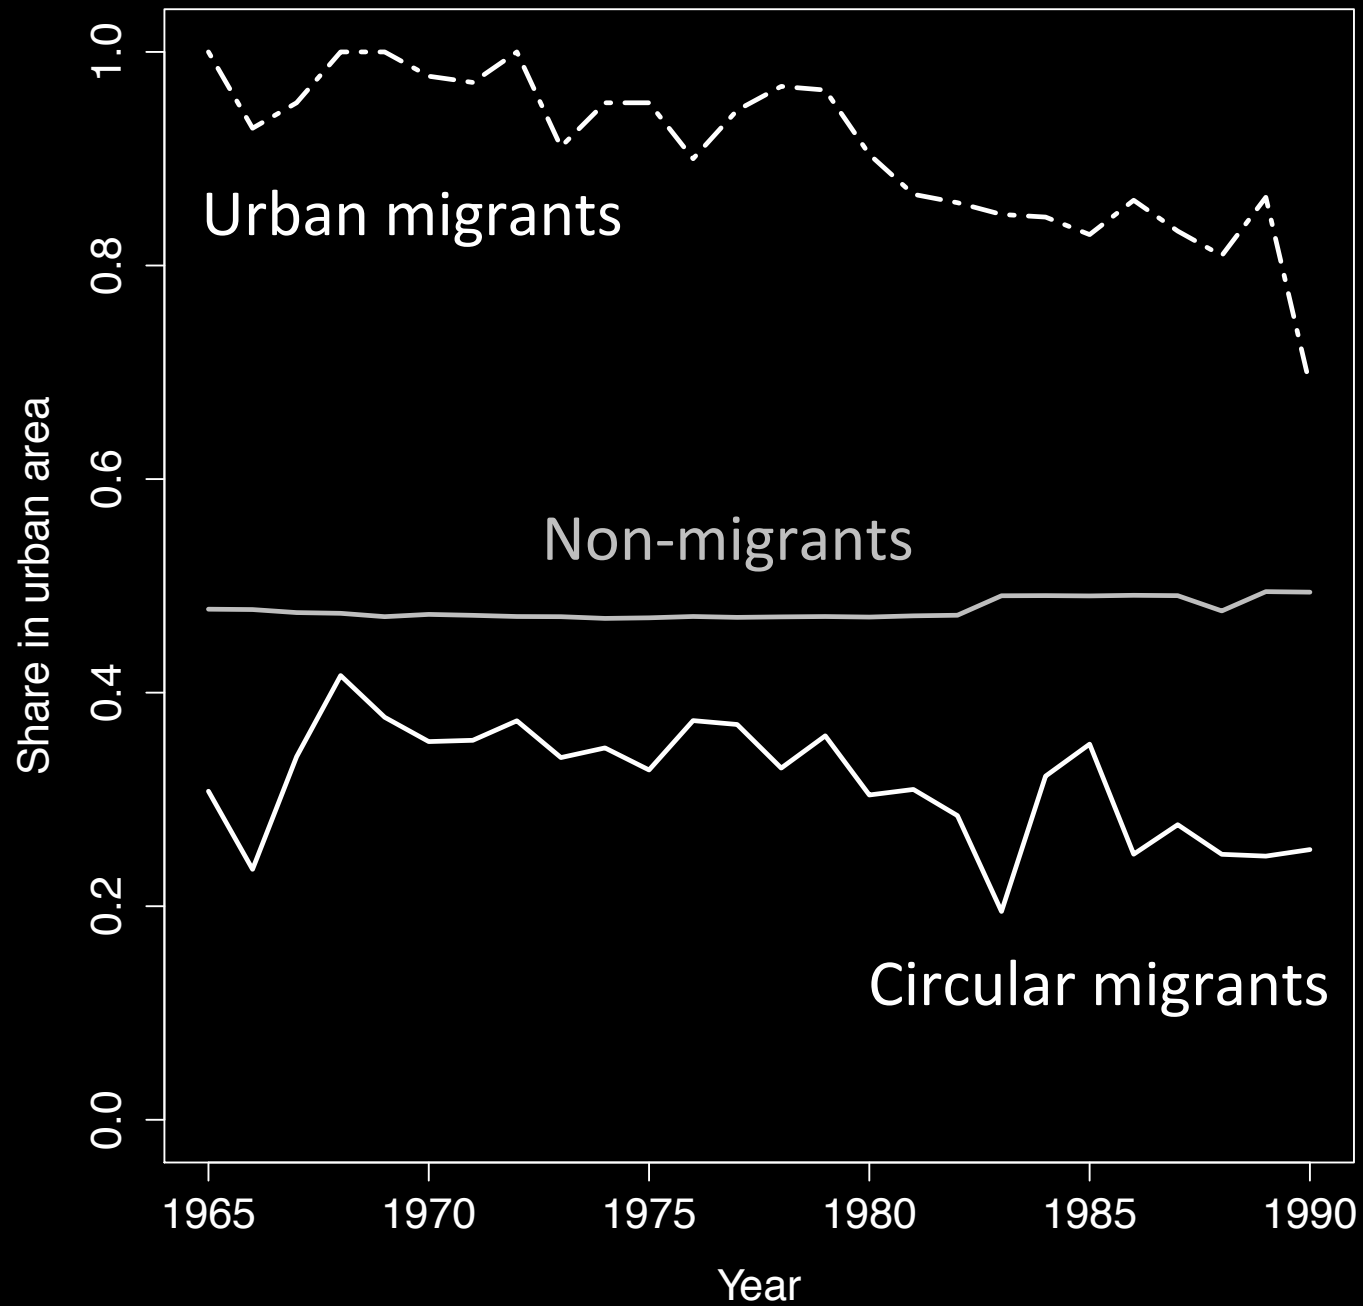

TRENDS IN EDUCATION

TRENDS IN URBAN RESIDENCE

TRENDS IN URBAN RESIDENCE

TRENDS IN WEALTH

TRENDS IN WEALTH

The distinct characteristics of each group are not just a reflection of changing Mexican population over time, but also of **changing selectivity** of migrants from that population.

Who migrates?

When?

Why?

Are different groups responding to
different **macro-level** conditions?

Neoclassical model	Low-skill wage in US GDP per capita in MX Unemployment in US Unemployment in MX Border patrol enforcement (BPE) budget
